

A certain N -Generalized Principally Quasi-Baer Subring of the Matrix rings

H. Haj Seyyed Javadi Amirkabir University

A. Moussavi, E. Hashemi: University of Tarbiat Modarres

Abstract

For a fixed positive integer n , we say a ring with identity is *n-generalized right principally quasi-Baer*, if for any principal right ideal I of R , the right annihilator of I^n is generated by an idempotent. This class of rings includes the right principally quasi-Baer rings and hence all prime rings. A certain n -generalized principally quasi-Baer subring of the matrix ring $M_n(R)$ are studied, and connections to related classes of rings (e.g., p.q.-Baer rings and n -generalized p.p. rings) are considered¹.

1. Introduction and Preliminaries

Throughout all rings are assumed to be associative with identity. From [12, 21], a ring R is (quasi-)Baer if the right annihilator of any (right ideal) nonempty subset of R is generated, as a right ideal, by an idempotent. Moreover, in [12] Clark proved the left-right symmetry of this condition. He uses this condition to characterize when a finite dimensional algebra with unity over an algebraically closed field is isomorphic to a twisted matrix units semigroup algebra. The class of quasi-Baer rings is a nontrivial generalization of the class of Baer rings. Every prime ring is quasi-Baer, hence prime rings with nonzero right singular ideal are quasi-Baer; but not Baer [24]. For a positive integer $n > 1$, the $n \times n$ matrix ring over a non-Prüfer commutative domain is a prime quasi-Baer ring which is not a Baer ring by [27] and [21, p.17]. The $n \times n$ ($n > 1$) upper triangular matrix ring over a domain which is not a division ring is quasi-Baer but not

Baer by an example due to Cohn; see [1], [20] and [5]. The theory of Baer and quasi-Baer rings has come to play an important role and major contributions have been made in recent years by a number of authors, including Birkenmeier, Chatters, Khuri, Kim, Hirano and Park (see, for example [1], [4-7], [16], [21], [26] and [28]).

A ring satisfying a generalization of *Rickart's condition* [30] (i.e., right annihilator of any element is generated (as a right ideal) by an idempotent) has a homological characterization as a right p.p.-ring. A ring R is called a *right* (resp. *left*) *p.p.-ring* if every principal right (resp. left) ideal is projective. R is called a *p.p.-ring* (also called a Rickart ring [2, p.18]), if it is both right and left p.p.-ring. In [9] Chase shows the concept of p.p.-ring is not left-right symmetric. Small [30] shows that a right p.p.-ring R is Baer (so p.p.), when R is orthogonally finite. Also it is shown by Endo [13] that a right p.p.-ring R is p.p. when R is abelian (i.e., every idempotent is central). Finally Chatters and Xue [11] prove that in a duo (i.e., every one sided ideal is two sided) p.p.-ring R , if I is a finitely generated right projective ideal of R , then I is left projective and a direct summand of an invertible ideal. Following Birkenmeier et al. [7], R is called *right principally quasi-Baer* (or simply *right p.q.-Baer*), if the right annihilator of a principal right ideal is generated by an idempotent. Equivalently, R is right p.q.-Baer if R modulo the right annihilator of any principal right ideal is projective. Similarly, left p.q.-Baer rings can be defined. If R is both right and left p.q.-Baer, then it is called p.q.-Baer. The class of p.q.-Baer rings includes all biregular rings, all quasi-Baer rings, and all abelian p.p.-rings. A ring R is said to be *p*-regular, if for every $x \in R$ there exists a natural number n , depending on x , such that $x^n \in x^n R x^n$. A ring R is called a *generalized right p.p.-ring* if for any $x \in R$ the right ideal $x^n R$ is projective for some positive integer n , depending on x , or equivalently, if for any $x \in R$ the right annihilator of x^n is generated by an idempotent for some positive integer n , depending on x . A ring is called *generalized p.p.-ring*, if it is both generalized right and left p.p.-ring.

Note that Von Neumann regular rings are right (left) p.p.-rings by Goodearl [14,

Theorem 1.1], and a same argument as [14, Theorem 1.1] shows that \mathbf{p} -regular rings are generalized p.p.-rings. Right p.p.-rings are generalized right p.p. obviously. See [18] for more details.

Definition 1.1. Given a fixed positive integer n , we say a ring R is n -generalized right principally quasi Baer (or \mathbf{n} -generalized right p.q.-Baer), if for all principal right ideal I of R , the right annihilator of I^n is generated by an idempotent. Left cases may be defined analogously.

The class of \mathbf{n} -generalized right p.q.-Baer rings includes all right p.q.-Baer rings, (and hence all biregular rings, quasi-Baer rings, abelian p.p.-rings and *semicommutative* (i.e., if $r(x)$ is an ideal for all $x \in R$) generalized p.p rings). Theorem 2.1 in section 2, allows us to construct examples of \mathbf{n} -generalized p.q.-Baer rings that are not p.q.-Baer. Some conditions on the equivalence of \mathbf{n} -generalized p.q.-Baer and \mathbf{n} -generalized p.p.-rings are discussed. However, we show by examples that the class of \mathbf{n} -generalized p.q.-Baer rings properly extends the aforementioned classes.

In this paper, we discuss some type of matrix rings formed over p.q.-Baer or p.p. rings. We study \mathbf{n} -generalized p.q.-Baer subrings of the matrix ring $M_n(R)$. Theorem 2.2, enables us to generate examples of \mathbf{n} -generalized p.q.-Baer subrings of the matrix ring $M_n(R)$. Theorem 2.2, which extends [18, Proposition 6], enables us to provide more examples of matrix rings, that are both \mathbf{n} -generalized p.q.-Baer and \mathbf{n} -generalized p.p.-ring. Connections to related classes of rings are investigated. Although the class of \mathbf{n} -generalized p.q.-Baer rings, includes all p.q.-Baer rings (and hence, all biregular rings, and all abelian p.p. rings), however we show by examples that the class of \mathbf{n} -generalized p.q.-Baer rings properly extends the aforementioned classes.

Note that, for a *reduced* ring (which has no nonzero nilpotent elements), we have $l_R(Rx) = l_R((Rx)^n) = l_R(x^n) = l_R(x) = r_R(x) = r_R(x^n) = r_R((xR)^n) = r_R(xR)$, for every $x \in R$ and every positive integer n . Therefore reduced rings are semicommutative and semicommutative rings are abelian. Also for reduced rings the definitions of right p.q.-

Baer, n -generalized right p.q.-Baer, generalized p.p. and p.p.-ring are coincide. This leads one ask whether commutative reduced rings are n -generalized p.q.-Baer. However, the answer is negative by the following.

Example 1.2. Let p be a prime number and $R = \{(a, b) \in Z \oplus Z \mid a \equiv b \pmod{p}\}$, then R is a commutative reduced ring. Note that the only idempotents of R are $(0, 0)$ and $(1, 1)$. One can show that $r_R((p, 0)R) = (0, p)R$, so $r_R((p, 0)R)$ dose not contain a nonzero idempotent of R ; and hence R is not n -generalized right quasi-Baer, for any positive integer n .

Lemma 1.3. Let R be an abelian n -generalized right p.q.-Baer ring, then $r_R(I^n) = r_R(I^m)$ for every principal right ideal I of R and each positive integer m with $n \leq m$.

Proof. It is enough to show that $r_R(I^n) = r_R(I^{n+1})$. Let $x \in r_R(I^{n+1})$, then $Ix \subseteq r_R(I^n) = fR$ for some idempotent $f \in R$. Hence $I^n x = I^n x f = 0$. Thus $x \in r_R(I^n)$.

2. \mathbf{N} -generalized right principally quasi Baer subrings of the matrix rings

In this section we discuss some type of matrix rings formed over p.q.-Baer or p.p. rings. Theorem 2.3, which extends [18, Proposition 6], enables us to provide more examples of matrix rings that are both n -generalized p.q.-Baer and n -generalized p.p.-ring. We begin with Theorem 2.2 below, which enables us to generate examples of n -generalized p.q.-Baer subrings of the matrix ring $M_n(R)$:

Lemma 2.1[18, Lemma 2]. Let R be an abelian ring and define

$$S_n := \left\{ \begin{pmatrix} a & a_{12} & \cdots & a_{1n} \\ 0 & a & \cdots & a_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & a \end{pmatrix} : a, a_{ij} \in R \right\},$$

with n a positive integer ≥ 2 . Then every idempotent in S_n is of the form

$$\begin{pmatrix} f & 0 & \cdots & 0 \\ 0 & f & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & f \end{pmatrix} \text{ with } f^2 = f \in R$$

We will use S_n Throughout the remainder of the paper, to denote the ring indicated in Lemma 2.1.

Theorem 2.2. If R is an abelian p.q.-Baer ring and $n (\geq 2)$ is a positive integer, then S_n is an n -generalized right p.q.-Baer ring.

Proof. We proceed by induction on n . It is easy to show that S_2 is a 2-generalized right p.q.-Baer ring. Let I_n be a principal right ideal of S_n . Consider $I_{n-1,1} = \{B \in S_{n-1} \mid B \text{ is obtained by deleting } n\text{-th row and } n\text{-th column of a matrix in } I_n\}$, and $I_{n-1,2} = \{B \in S_{n-1} \mid B \text{ is obtained by deleting } 1\text{-th row and } 1\text{-th column of a matrix in } I_n\}$. It is clear that $I_{n-1,1}$ and $I_{n-1,2}$ are principal right ideals of S_{n-1} . By induction hypothesis and Lemma 2.1, there are $e_i^2 = e_i \in S_{n-1}$, $f_i^2 = f_i \in R$ for $i = 1, 2$ such that $r_{S_{n-1}}(I_{n-1,i}^{n-1}) = e_i S_{n-1}$, $e_i = \begin{pmatrix} 0 & f_i & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & x \end{pmatrix}$. Let J be the set of entries of the main diagonal of the elements of $I_{n-1,1}$ or $I_{n-1,2}$. It is clear that J is a principal right ideal of R . Since R is right p.q.-Baer, $r_R(J) = f_1 R = f_2 R$. Hence $f_1 = f_2$, since R is an abelian ring. Now let

$$X = \begin{pmatrix} x & x_{12} & \cdots & x_{1n} \\ 0 & x & \cdots & x_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & x \end{pmatrix} \in r_{S_n}(I_n^n) \text{ and } Y = \begin{pmatrix} a_1 a_2 a_3 \cdots a_n & y_{12} & \cdots & y_{1n} \\ 0 & a_1 a_2 a_3 \cdots a_n & \cdots & y_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & a_1 a_2 a_3 \cdots a_n \end{pmatrix} \in I_n^n$$

Since $r_{S_{n-1}}(I_{n-1,1}^{n-1}) = r_{S_{n-1}}(I_{n-1,2}^{n-1}) = e_1 S_{n-1}$, x and x_{ij} 's are in $f_1 R$ for each i and j except x_{1n} . So we have $a_1 a_2 \cdots a_n x_{1n} + y_{1n} x = 0$. Hence $y_{1n} x = 0$, since $f_1 \in B(R)$. Thus $x_{1n} \in f_1 R$ and hence $r_{S_n}(I_n^n) \subseteq e S_n$ for

$$e = \begin{pmatrix} f_1 & 0 & \cdots & 0 \\ 0 & f_1 & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & f_1 \end{pmatrix} \in S_n.$$

Since, for each $Y \in I_n e$, all entries of the main diagonal of Y are zero and e is central, $I_n^n e = (I_n e)^n = 0$. Thus $r_{S_n}(I_n^n) = e S_n$. Therefore S_n is n -generalized right p.q.-Baer.

The following result, which generalizes [18, Proposition 6], provides examples of

matrix rings that are both n -generalized p.q.-Baer and n -generalized p.p.-ring:

Theorem 2.3. If R is an abelian p.p.-ring, then S_n is an abelian n -generalized p.p.-ring.

Proof. We prove by induction on n . First, we show that the trivial extension S_2 of R is

2-generalized right p.p. Let $A = \begin{pmatrix} a & b \\ 0 & a \end{pmatrix} \in S_2$ and $r_R(a) = eR$, with $e = e^2 \in R$. It is clear

that, $fR \subseteq r_{S_2}(A^2)$ with $f = \begin{pmatrix} e & 0 \\ 0 & e \end{pmatrix}$. Next, let $A^2 \begin{pmatrix} x & y \\ 0 & x \end{pmatrix} = 0$. Since R is reduced,

$a^2x = ax = 0$ and $a^2y = ay = 0$. Hence $ex = x$ and $y = ey$. Thus $\begin{pmatrix} x & y \\ 0 & x \end{pmatrix} = f \begin{pmatrix} x & y \\ 0 & x \end{pmatrix}$.

Therefore S_2 is 2-generalized right p.p. Now assume $B = \begin{pmatrix} a & a_{12} & \cdots & a_{1n} \\ 0 & a & \cdots & a_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & a \end{pmatrix} \in S_n$.

Consider $B_1 = \begin{pmatrix} a & a_{12} & \cdots & a_{1n-1} \\ 0 & a & \cdots & a_{2n-1} \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & a \end{pmatrix}$ and $B_2 = \begin{pmatrix} a & a_{23} & \cdots & a_{2n} \\ 0 & a & \cdots & a_{3n} \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & a \end{pmatrix}$ in S_{n-1} , then by the

induction hypothesis, there exists $e_i^2 = e_i \in S_{n-1}$, $f_i^2 = f_i \in R$, such that $r_{S_{n-1}}(B_i^{n-1}) = e_i S_{n-1}$,

$e_i = \begin{pmatrix} f_i & 0 & \cdots & 0 \\ 0 & f_i & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & f_i \end{pmatrix}$ for $i = 1, 2$. By direct calculations, we have $r_{S_n}(B^{2n-2}) = e S_n$ with

$e = \begin{pmatrix} f & 0 & \cdots & 0 \\ 0 & f & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & f \end{pmatrix}$. Since $r_R(a) = fR$, by [27, Lemma 3], $r_{S_n}(B^n) = r_{S_n}(B^{2n-2}) = e S_n$.

Corollary 2.4 [18, Proposition 6]. If R is a domain, then S_n is an abelian n -generalized p.p.-ring.

For a semicommutative ring, the definitions of n -generalized right p.q.-Baer and n -generalized right p.p. are coincide:

Proposition 2.5. Let R be a semicommutative ring. Then R is n -generalized right p.q.-Baer if and only if R is n -generalized right p.p.

Proof. Let R be n -generalized right p.q.-Baer and $a \in R$. Then $r_R(aR)^n = eR$ for some idempotent $e \in R$. Let $x \in r_R(a^n)$. Since R is semicommutative, $RaRx \subseteq r_R(a^{n-1})$, which implies that $r_R(aR)^n = eR$. The converse is similar.

There exists an \mathbf{n} -generalized right p.q.-Baer ring, which is generalized p.p.-ring but is not semicommutative.

Example 2.6. Let R be an integral domain and S_4 be defined over R . Then S_4 is abelian 4-generalized p.p.-ring and is 4-generalized p.q.-Baer by Corollary 2.4. By considering $b = a = e_{12} + e_{14} + e_{34}$ and $c = e_{23}$ in S_4 , where e_{ij} denote the matrix units, we have $ab = 0$, and $acb \neq 0$, hence $aS_4b \neq 0$.

Now we conjecture that subrings of \mathbf{n} -generalized right p.q.-Baer rings are also \mathbf{n} -generalized right p.q.-Baer. But the answer is negative by the following.

Example 2.7. For a field F , take $F_n = F$ for $n = 1, 2, \dots$, and let S be the 2×2 matrix ring over the ring $\prod_{n=1}^{\infty} F_n$. By [7, Proposition 2.1 and Theorem 2.2] we have that S is a p.q.-Baer ring. Let

$$R = \left(\begin{array}{cc} \prod_{n=1}^{\infty} F_n & \bigoplus_{n=1}^{\infty} F_n \\ \bigoplus_{n=1}^{\infty} F_n & \langle \bigoplus_{n=1}^{\infty} F_n, 1 \rangle \end{array} \right),$$

which is a subring of S , where $\langle \bigoplus_{n=1}^{\infty} F_n, 1 \rangle$ is the F -algebra generated by $\bigoplus_{n=1}^{\infty} F_n$ and 1. Then by [7, Example 1.6], R is semiprime p.p. which is neither right p.q.-Baer (and hence not \mathbf{n} -generalized right p.q.-Baer), nor left p.q.-Baer (and hence not \mathbf{n} -generalized left p.q.-Baer).

3. Examples of \mathbf{n} -generalized p.q.-Baer subrings

Although the class of \mathbf{n} -generalized p.q.-Baer rings, includes all p.q.-Baer rings (and hence, all biregular rings, all quasi-Baer rings, and all abelian p.p. rings), however we show by examples that the class of \mathbf{n} -generalized p.q.-Baer rings properly extends the aforementioned classes.

By the following example, there is an abelian p.q.-Baer (hence semiprime) ring R ,

which is not reduced, but S_n is an abelian n -generalized right p.q.-Baer ring that is not semiprime.

Example 3.1. By Zalesskii and Neroslavskii [10, Example 14.17, p.179], there is a simple noetherian ring R that is not a domain and in which 0 and 1 are the only idempotents. Thus R is an abelian p.q.-Baer ring that is neither left nor right p.p., and hence is not reduced. By [7, Proposition 1.17] R is semiprime and by Theorem 2.1, S_n is abelian n -generalized p.q.-Baer, that is not semiprime and hence is not right p.q.-Baer.

Example 3.2. If R is an abelian p.q.-Baer ring, then $R[x]/\langle x^3 \rangle$ is an n -generalized p.q.-Baer ring.

Proof. First we note that $\Theta : T \rightarrow R[x]/\langle x^3 \rangle$ defined by

$$(a_0, a_1, a_2) \rightarrow (a_0 + a_1x + a_2x^2) + \langle x^3 \rangle$$

is an isomorphism, where $T = \{(a, b, c) \mid a, b, c \in R\}$ is a ring with addition componentwise and the multiplication defined by

$$(a_1, b_1, c_1) \cdot (a_2, b_2, c_2) = (a_1a_2, a_1b_2 + b_1a_2, a_1c_2 + b_1b_2 + c_1a_2).$$

Let J be an ideal of T . Suppose $I = \{a \in R \mid (a, b, c) \in J\}$, it is clear that I is an ideal of R . Since R is p.q.-Baer, $r_R(I) = eR$ for an idempotent $e \in R$. We can show that $r(J^3) = (e, 0, 0)T$, and hence, the result follows.

There exists a commutative n -generalized p.q.-Baer (hence n -generalized p.p.-) ring R , over which S_n is not an n -generalized p.p.-ring.

Example 3.3. Let $p \neq 3$ be a prime integer and Z_{p^3} be the ring of integers modulo p^3 , and S_3 be defined over Z_{p^3} . Let $A = pI_3 + e_{13}$, where I_3 is the identity matrix and e_{ij} denote the matrix units. It is clear that $pI_3 + e_{13} + e_{12} \in r_{S_n}(A^3)$ and idempotents of S_3 are I_3 and 0. Hence $r_{S_3}(A^3) \neq I_3S_3$ and that S_3 is not 3-generalized p.p.-ring, but Z_{p^3} is a 3-generalized p.p.-ring.

Example 3.4. For every abelian quasi-Baer (resp. p.p.-) ring R , by Theorems 2.1 and

2.2, the ring S_n is n -generalized right p.q.-Baer, which is not right p.q.-Baer. Therefore we are able to provide examples of n -generalized right p.q.-Baer rings that is not right p.q.-Baer:

Let F be a field, and $R = F[x]$ be the polynomial ring where x is an indeterminate. Then S_n is a n -generalized right p.q.-Baer ring that is not right p.q.-Baer.
